1 **Abstract**

2 **Over the past 20 years, monitoring in soccer has become increasingly popular for**
3 **managing training loads, preventing injuries, and optimizing performance. However,**
4 **implementing sophisticated systems demands substantial investment in equipment, staff**
5 **training, and athlete time¹.** The present study aimed to evaluate player's perceptions around
6 a comprehensive athlete monitoring programme used within a professional English men's
7 soccer team. A mixed-methods sequential explanatory design was employed across two phases.
8 In Phase one, 20 professional male soccer players completed a 'Modified Athlete Attitudes and
9 Beliefs Questionnaire'. The results from Phase 1 informed Phase 2, where a subset of
10 participants (n = 10) engaged in semi-structured interviews to gain deeper insights into their
11 attitudes and perceptions of athlete monitoring. Analysis revealed that GPS monitoring was the
12 most favoured tool, while power monitoring (countermovement jump; CMJ) was the least
13 preferred. Thematic analysis of interview data identified an overall theme of importance,
14 broken down into four key themes: education, feedback, adjustment period, and specific
15 monitoring tools. To enhance athlete engagement, practitioners should emphasize the relevance
16 of each monitoring strategy to the athletes' performance. Streamlining monitoring strategies
17 and providing more comprehensive feedback can foster greater athlete buy-in and adherence
18 to monitoring programmes.

19 **Key Words:** Monitoring; Soccer; Questionnaire; Interviews; Qualitative

26 **Introduction**

27 In soccer, training for physical performance has become a specialised area that requires a
28 multidisciplinary approach^{2,3}, often involving sports scientists, strength and conditioning
29 coaches, and other support staff⁴. This complex ecosystem of athlete development has led to
30 the growing adoption of various athlete monitoring tools and strategies, including but not
31 limited to global positioning system (GPS) tracking, force platforms, and subjective wellness
32 assessments⁵⁻⁹. Monitoring and evaluating athletes' performance and well-being are now
33 integral to managing training loads, preventing injuries, and optimising performance
34 outcomes¹⁰. The implementation of such sophisticated monitoring systems is, however,
35 resource-intensive, requiring significant financial investment in equipment, specialised training
36 for staff, and time commitment from athletes¹. Although technological advancements have
37 made athlete monitoring more accessible, there remain significant challenges in translating the
38 data into actionable insights for coaching staff and athletes alike¹¹. **This disconnect often
39 stems from several factors, despite the increasing employment of practitioners with sport
40 science and strength and conditioning expertise. One major issue is the sheer volume of
41 data generated, which can overwhelm practitioners and coaches who may lack the time
42 or capacity to analyse it effectively¹². Additionally, the data's utility can be undermined
43 by insufficient communication between practitioners and key stakeholders, such as
44 coaches or athletes, resulting in a failure to integrate insights into training and
45 performance strategies¹². Understanding how athletes perceive these monitoring strategies is
46 critical, as their compliance and engagement are key factors that determine the utility of the
47 data collected^{13,14}. **Previous research has shown that an athlete's sustained effort is
48 significantly influenced by their perception of the usefulness of subjective wellness
49 monitoring tools¹⁵. Athlete monitoring is often viewed favourably by practitioners for its
50 ability to provide objective data that can inform training decisions and enhance performance****

1
2
3 51 outcomes¹⁴. However, the athlete's perspective is equally important but often overlooked¹¹. If
4
5 52 athletes do not understand the purpose or perceive a value in the monitoring process, they may
6
7
8 53 be less inclined to engage fully, which can undermine the reliability of the data collected¹⁶.
9
10 54 Research has highlighted several barriers to athlete compliance, including lack of perceived
11
12 55 need, discomfort with equipment, and social factors such as peer influence and coaching
13
14 56 pressure¹⁷⁻¹⁹.

15
16
17
18 57 **Recent research has sought to combine quantitative and qualitative measures to offer a**
19
20 58 **more holistic understanding of athlete fatigue and readiness for training**²⁰. This mixed-
21
22 59 methods approach is particularly valuable as it allows for a more nuanced interpretation of data,
23
24 60 capturing both the physiological and psychological dimensions of athlete performance and
25
26 61 well-being²¹. For example, while quantitative data might reveal trends in physical performance
27
28 62 or recovery, qualitative insights can help explain the underlying attitudes and perceptions that
29
30 63 drive these trends²². By triangulating data from various sources, researchers can generate a
31
32 64 richer, more detailed picture of an athlete's overall condition, potentially improving
33
34 65 intervention strategies and training outcomes.

35
36
37
38
39
40 66 Despite the growth in research around athlete monitoring, the majority of studies have
41
42 67 primarily focused on practitioner perspectives²³ or the technical efficacy of monitoring tools⁶,
43
44 68 with limited attention given to the athlete's viewpoint. As previously stated, gaining athlete
45
46 69 buy-in is essential for ensuring strong adherence to monitoring protocols and understanding
47
48 70 athletes' perceptions can help practitioners optimise this process²⁴. Factors such as transparency
49
50 71 in data usage, frequency of monitoring, and the clarity of feedback are crucial determinants of
51
52 72 athlete engagement and can significantly shape their attitudes towards monitoring tools²⁵. For
53
54 73 instance, recent research has shown that athletes often prefer feedback that allows them to
55
56 74 benchmark their performance against peers in similar playing positions²⁵. This highlights the
57
58
59
60

1
2
3 75 competitive nature of professional soccer and suggests that feedback mechanisms could be
4
5 76 optimized by providing context-specific comparisons to enhance motivation and adherence.
6
7
8 77 Furthermore, the method and timing of feedback delivery—whether it is visual, verbal, or
9
10 78 written—can also play a pivotal role in shaping athlete perceptions. Positive reinforcement and
11
12 79 constructive communication between practitioners and athletes can help build a culture of trust
13
14 80 and openness, thereby enhancing athletes' perceived value of monitoring tools²⁶ and optimising
15
16 81 the process for practitioners. There is a growing need to explore how athletes' perceptions vary
17
18 82 based on factors such as age, experience, and position within the team. Understanding these
19
20 83 factors will allow practitioners to understand the environment to optimise the use of monitoring
21
22 84 tools. For example, younger athletes or those with less exposure to monitoring protocols may
23
24 85 require a longer adjustment period to fully appreciate the benefits of these tools¹⁵. More
25
26 86 experienced athletes might have different expectations and levels of engagement¹⁴.
27
28
29 87 **Practitioners** should consider these factors when designing and implementing monitoring
30
31 88 programs to ensure they are tailored to the specific needs and preferences of diverse athlete
32
33 89 groups.
34
35
36
37
38

39 90 The present study aimed to address this gap by exploring the attitudes and perceptions of
40
41 91 professional soccer players towards various athlete monitoring tools using a mixed-methods
42
43 92 approach. By utilising both surveys and qualitative semi-structured interviews, the study
44
45 93 sought to provide a more holistic understanding of how monitoring tools are perceived and
46
47 94 how these perceptions may influence adherence and engagement. This research contributes to
48
49 95 the broader discussion on optimising athlete monitoring practices in professional soccer and
50
51 96 offers practical recommendations for enhancing athlete buy-in and the overall effectiveness of
52
53 97 monitoring programs.
54

57
58
59 98
60

99 **Materials and Methods**

100 *Methodology*

101 The present study adopted a **pragmatist approach** to explore the perceptions and attitudes of
102 professional soccer players towards athlete monitoring. Pragmatism focuses on practical
103 solutions and the use of varied approaches to understand complex phenomena, making it
104 particularly effective within the context of a Championship soccer club. This approach is well-
105 suited for integrating both quantitative and qualitative data²². The pragmatist approach guided
106 the study's design, enabling the collection of broad patterns through quantitative data and
107 deeper, contextual insights through qualitative data. This study utilised a mixed-methods
108 sequential explanatory design (**see figure 1**), consisting of two phases: an initial phase using
109 questionnaires, followed by a qualitative phase using semi-structured interviews²⁷. This
110 approach ensures that the quantitative findings are enriched by qualitative insights, facilitating
111 a comprehensive understanding of the complexities in athletes' attitudes.

112 In Phase 1, athlete perceptions were gathered using a questionnaire that contained a mixture of
113 Likert-scale responses and open-ended questions. This phase established general trends and
114 themes in the athletes' attitudes around monitoring tools. In Phase 2, comprehensive semi-
115 structured interviews were conducted to allow participants to elaborate on their responses
116 captured by the questionnaires and provide detailed explanations of their attitudes towards
117 athlete monitoring. **The combination of quantitative and qualitative methods of data**
118 **collection developed the study's validity and provided a more detailed and nuanced**
119 **perspective**²². In line with the explanatory approach, thematic analysis strategies were
120 employed to develop key themes from the qualitative data, thereby providing a holistic view
121 of the participants' experiences and perceptions.

122 *Participants*

1
2
3 123 Institutional ethics (ref:125255) from the host institute was granted before the start of the study.
4
5 124 The study was conducted in accordance with the declaration of Helsinki. Twenty elite male
6
7
8 125 soccer players (age = 25 ± 5 years; height = 1.83 ± 0.09 m and body mass = 84 ± 5.5 kg) from
9
10 126 the English Championship participated in this study. The participants held a mean experience
11
12 127 as a professional of $6 \text{ years} \pm 3 \text{ years}$. All the players had completed the same athlete monitoring
13
14 128 processes during the 20/21 season. **This number of participants was deemed appropriate**
15
16
17 129 **as it reflects a homogeneous sample representative of elite soccer players at this**
18
19 130 **competitive level. Additionally, recruiting players from a single team ensured consistent**
20
21 131 **exposure to training, competition schedules, and monitoring protocols, thereby**
22
23 132 **enhancing the reliability of the data collected.**
24
25

26 133

27
28 134 *First Phase*

29
30 135 Participants were given information sheets, to outline the purpose of the study²⁸. The document
31
32 136 highlighted that participants would be kept anonymous throughout. Participants (N = 20)
33
34 137 initially completed a questionnaire at their own convenience on their mobile phone which was
35
36 138 designed, distributed, and managed using Jisc Online Surveys²⁹ in April & May, at the end of
37
38 139 the 20/21 season. Those that opted to participate accessed the survey via a secure link. The
39
40 140 questionnaire was a modified version of the athlete attitudes and beliefs questionnaire used in
41
42 141 previous research³⁰ and was shaped based on feedback from experts within the field. The goal
43
44 142 of the first phase was to identify the athletes' attitudes and experiences around individual
45
46 143 monitoring strategies of GPS, subjective wellness, power, strength, and saliva testing. **GPS**
47
48 144 **tracking (Catapult) was utilized for every training session and match, with players**
49
50 145 **wearing a compact unit embedded in a specially designed sports vest. Subjective wellness**
51
52 146 **was assessed via a four-question questionnaire on the 'Catapult AMS' app. This included**
53
54 147 **recording sleep hours and using Likert-scale responses to evaluate muscle soreness,**
55
56
57
58
59
60

1
2
3 148 **fatigue, and sleep quality. Power monitoring involved measuring countermovement**
4
5 149 **jumps using dual force plates (FDLite, Vald Performance, Newstead, Australia). Strength**
6
7 150 **testing included assessments of hip adduction and abduction strength with the VALD**
8
9 151 **ForceFrame (Vald Performance, Newstead, Australia), as well as isometric prone**
10
11 152 **hamstring strength testing with the VALD NordBord. Saliva samples were collected using**
12
13 153 **synthetic polymer-based oral swabs (Soma Bioscience, IPRO Interactive, UK) to measure**
14
15 154 **immunoglobulin A (IgA) and cortisol levels.** These were the predominant & most frequently
16
17 155 tested variables within the club, **chosen by the head of Physical Performance.** Questions
18
19 156 based on attitudes and experiences around the importance, frequency and benefits of athlete
20
21 157 monitoring were asked. The core of the survey was made up of twelve seven-point Likert scale
22
23 158 questions, ranging from extremely good/likely to extremely bad/unlikely, alongside a small
24
25 159 number of free text questions. A list of questions can be found in the supplementary material
26
27 160 **in appendix 1.**
28
29
30
31
32

161

162 *Second Phase*

163 In the second phase, a subset of players (N = 10) completed a one-to-one interview by the
164 primary author. We purposely selected athletes with a range of age, experience, and responses
165 to the first phase of the study, including ≥ 2 individuals from each age group (<21, 21-25, 26-
166 30, 31+ years old) & experience group (1-3, 3-6, 6-9, 9+ years professional experience). **These**
167 **groups were selected to ensure the results represented a balanced range of ages and levels**
168 **of experience.** The primary author had recently left their role employed at the football club as
169 a physical performance coach, where he had worked closely with this group of athletes for ~3
170 years. The author had ~9 years of experience working with & monitoring athletes, and held a
171 BSc and MSc, alongside UKSCA accreditation, at the time of interview. **Reflexivity was**
172 **employed to minimize researcher bias, with the primary author continuously reflecting**

1
2
3 173 **on their position as both a former practitioner in the athletes' environment and as a**
4
5 174 **researcher³¹. This reflective practice was critical in maintaining objectivity during data**
6
7
8 175 **collection and analysis.** The interviews took place between the interviewer and participant
9
10 176 online using Zoom Cloud Meetings³². Due to the close nature of the relationship between the
11
12 177 author and athletes, the high-quality rapport meant that online interviews were appropriate. The
13
14 178 fact that the interviewer was also no longer employed by the club at the time of interview, may
15
16 179 have helped to lead to a more open discussion. Interviews lasted between 20-55 minutes (mean
17
18 = 32 minutes); a semi-structured interview was developed to allow novel ideas to develop and
19
20 180 diverse perceptions to be expressed³³. This flexible approach allowed for unexpected findings
21
22 181 to emerge, with participants unrestricted by pre-set questions. The facilitator received extensive
23
24 182 training, exceeding 30 hours, in interviewing techniques and analysis and pilot data was
25
26 183 captured. The interview started with questions around their previous experiences of player
27
28 184 monitoring and how their experiences have changed since the start of their career. Following
29
30 185 this, each interviewee was asked about the specific areas of monitoring (GPS, subjective
31
32 186 wellness, strength, power and saliva testing) and was asked to explain why they picked their
33
34 187 rating score from the original questionnaire. To gain further insight, athletes were then asked
35
36 188 to elaborate on their questionnaire answers around the most positive and negative areas of
37
38 189 athlete monitoring. The questions in the interview aimed to achieve the richest possible data³⁴.
39
40 190 They were open ended³⁵, not leading³⁴, and aimed to generate answers that were unique³⁶ and
41
42 191 in depth³⁷. Whilst the broad structure of the interviews were the same, the order of questions
43
44 192 was dependent on participants responses and allowed easy movement from question to
45
46 193 question³⁸. **Following the first interview, a review process was initiated, wherein the**
47
48 194 **critical friend (~12 years' experience) viewed the recording and provided feedback to**
49
50 195 **ensure the interview was conducted naturally and organically. The critical friend**
51
52 196 **provided ongoing constructive criticism to the primary researcher, which contributed to**
53
54
55
56
57
58
59
60

1
2
3 198 **enhancing the depth of the interview content and ensuring rigor in data collection** ³⁹. The
4
5 199 **critical friend encouraged data collection to continue through interviews until data**
6
7 200 **saturation was reached, and no new themes emerged. This iterative process served to**
8
9 201 **refine the interview technique and ensure that the participants' responses were not**
10
11 202 **influenced by leading questions. Each interview transcript was thoroughly familiarised**
12
13 203 **by the primary author to ensure immersion in the data, allowing for a more profound**
14
15 204 **understanding of the athletes' experiences.** Critical junctures in data collection and analysis
16
17 205 involved collaborative discussions with the broader research team, comprised of individuals
18
19 206 possessing substantial qualitative expertise. These meetings focused on exploring emerging
20
21 207 themes and subthemes **from the interview transcripts**, as well as comparing the anticipated
22
23 208 findings of the interviewer with the actual trends revealed by the data and assessing the point
24
25 209 at which data saturation had occurred. An overview of the methodology can be seen below in
26
27 210 figure 1. The COREQ checklist for this study can be found as supplementary material in
28
29 211 appendix 2.

30

57
58
59
60

1
2
3 223 **Statistical Analysis**
4

5 224 *Questionnaire Analysis*
6

7
8 225 Descriptive statistics, including means, standard deviations, and response frequencies, were
9
10 226 calculated for each questionnaire item to summarize the general attitudes of athletes toward
11
12 227 various monitoring tools. Likert scale responses were analysed using frequency distribution to
13
14 228 identify trends and highlight prevalent attitudes. Key themes were established through free-text
15
16 229 questions and comments.
17

18
19 230

20
21 231 *Semi-structured interview analysis*
22

23
24
25 232 The interviews were recorded and transcribed using the 'Rev' transcription software integrated
26
27 233 with Zoom. Post-transcription, the primary author reviewed and amended the transcripts to
28
29 234 ensure accuracy by cross-referencing with the live recordings⁴⁰. Given the elite nature of the
30
31 235 athletes involved, the transcripts are not publicly available to maintain confidentiality, as the
32
33 236 detailed responses could lead to the identification of the participants. To preserve the integrity
34
35 237 of the data, the anonymization process was rigorously followed. The data was analysed using
36
37 238 an inductive thematic analysis approach^{41,42}. This method was selected for its flexibility and its
38
39 239 ability to generate themes directly from the data, as opposed to being restricted by predefined
40
41 240 theoretical frameworks. This approach is particularly useful when exploring new or under-
42
43 241 researched areas, such as elite athletes' perceptions of monitoring tools, as it allows themes to
44
45 242 emerge naturally from the data⁴³. The thematic analysis was conducted in six phases^{41,42}. Each
46
47 243 stage of analysis was critically evaluated with the support of the critical friend to ensure
48
49 244 consistency and reliability in the interpretation of themes. To ensure methodological rigor,
50
51 245 additional measures such as reflexivity and the use of an audit trail were implemented. The
52
53 246 audit trail⁴⁴ documented each step of the research process, providing transparency and enabling
54
55 247 the replication of the study by future researchers. The combination of rigorous data analysis
56
57
58
59
60

1
2
3 248 techniques and reflective practices ensured that the themes generated from the qualitative data
4
5 249 were both valid and reliable, offering rich insights into athletes' perceptions and attitudes
6
7
8 250 toward monitoring tools.
9

10
11 251
12 252 **Results**

13
14 253 *Questionnaire's*

15
16
17 254 A total of N=20 participants completed the questionnaire. When asked about specific
18
19 255 monitoring tools, GPS was rated as the most popular, with 90% (N = 18) rating it as quite to
20
21 256 extremely good. Power monitoring was rated as the least popular, with 25% (N = 5) rating it
22
23
24 257 as quite to extremely bad. Table 1 highlights the individual responses to specific monitoring
25
26 258 tools.
27

28 259
29
30 260 *Table 1. Individual responses to overall athlete monitoring, and specific monitoring tools*
31
32

10 275 [Insert Table 2]

11
12 276

13
14
15 277

16
17 278 Players were also asked, using free text questions, to highlight the positive and negative aspects
18
19 279 of athlete monitoring. Frequent positive responses (**n = 4**) included ‘seeing progress over time’
20
21 280 and ‘accurate feedback’. Frequent negative responses (**n = 5**) included ‘too frequent’ and
22
23 281 ‘taking too long’. The feedback from the questionnaires informed the semi-structured
24
25 282 interviews that followed.

26
27
28 283

29
30 284 *Semi-structured interviews*

31
32
33 285 We conducted a thematic analysis of the text data **from the interview transcripts**. One key
34
35 286 theme was developed, which was split up into four contextual themes. The key theme
36
37 287 developed was importance, which was split up into four themes of: education, feedback,
38
39 288 adjustment period, and specific monitoring tools. Each theme was broken down into further
40
41 289 sub themes.

42
43
44 290

49
50
51 295

52 296 *Feedback*

53 297

54
55 298 **Feedback was defined as the process of providing athletes with the results obtained from**
56
57 299 **monitoring.** Feedback was highlighted as an important area by all (n = 10) of the interviewees.

58
59 300 Feedback was broken down into further sub-themes of longitudinal monitoring, readiness to
60

1
2
3 301 train, objective data, conversations, and visual feedback. Objective data was consistently
4
5 302 regarded as reliable and trustworthy, with one athlete commenting on the strength testing
6
7
8 303 equipment:

9
10 304 *'It's never gonna give you false information' athlete 8.*

11
12 305 **Several interviewees highlighted the benefits of visual and real-time feedback, such as**
13
14 306 **using an iPad to display strength test scores. Athletes frequently described receiving**
15
16 307 **'objective' and 'hard' feedback as a positive experience. This suggests that athletes may**
17
18 308 **perceive 'objective' testing, particularly when accompanied by instant visual feedback,**
19
20 309 **as more trustworthy and valuable.**

21
22
23 310 *'I really like numbers and stuff, so I really liked it (the monitoring). It is something I had*
24
25 311 *never seen before, with the tech(nology), and the numbers in front of you. It were the first*
26
27 312 *time I ever did testing to see like your max sprint speed. And I surprised myself, because I*
28
29 313 *never thought I were that quick... That's where I got interested in the numbers that came*
30
31 314 *out of the testing scenarios,' Athlete 7.*

32
33
34 315 **The GPS monitoring system was the only tool utilized during both training sessions and**
35
36 316 **matches, providing real-time feedback to athletes. Live GPS data was recorded and**
37
38 317 **subsequently shared with players through match reports, aligning with the sub-themes**
39
40 318 **of Objective Data and Visual Feedback. Similarly, strength and power monitoring tools**
41
42 319 **incorporated both visual and verbal feedback, enhancing athletes' understanding of their**
43
44 320 **performance and fostering trust in the results. In contrast, no routine feedback was**
45
46 321 **provided for saliva or wellness monitoring tools, except when results significantly**
47
48 322 **deviated from the athletes' baseline in which conversations were initiated by support**
49
50 323 **staff. This selective feedback approach highlights how 'readiness to train' and**
51
52 324 **'conversations' are prioritized for tools with immediate relevance to athletic**
53
54 325 **performance.**
55
56
57
58
59
60

1
2
3 3264
5 327 *Education*

6
7
8 328 Education was highlighted as another key theme within the research, as mentioned by 90% (n
9 = 9) of the interviewees. Specifically, a lack of education, was stated as a critical part of
10 329 importance. **Saliva testing was cited most frequently as having a lack of education (n = 6),**
11
12 330 Novel tests were highlighted as needing more education, with constant feedback being linked
13
14 331 to improved education and understanding;
15
16 332

17
18 333 *'This was a new one (saliva testing), and I didn't really understand what you was getting out*
19
20 334 *of that. I know you've explained it. But I get that, if that is the next level for better recovery,*
21
22 335 *then I'm all for it. Because this was introduced this season for the first time, and I didn't see*
23
24 336 *any feedback from it, not sure if I was educated enough on it. That was the one to be fair, that*
25
26 337 *I could do with learning more about.'* Athlete 10

27
28
29 338 Saliva testing, as a novel test, was found to have the highest number of 'neither' (N=6), when
30
31 339 asked how it was perceived. This may be linked to the lack of education, with athletes being
32
33 340 unsure of the usefulness of the test.

34
35
36 341 *'That one (saliva testing) kind of threw me off when we were introduced it. Cause I've*
37
38 342 *never even heard of it or seen it before. And I think for me, I didn't know. I think you*
39
40 343 *needed more of an understanding. I didn't really know, well, I didn't understand exactly*
41
42 344 *what it was testing.'* Athlete 1.

43
44
45 345 Athlete one emphasizes that not understanding the purpose of the test or how it could
46
47 346 enhance performance may have limited their engagement. This lack of education
48
49 347 potentially reduced their sense of the test's importance.

50
51 34852
53
54 349 *Adjustment Period*
55
56
57
58
59
60

1
2
3 350 **Within this paper, the adjustment period can be defined as the time it can take for an**
4
5 351 **athlete to become accustomed to a new monitoring strategy, following their first exposure.**
6
7 352 **The adjustment period allows for the athletes to understand what the process of testing**
8
9 353 **is, how to perform the test and how the results would be used.** Five factors were identified
10
11 354 as influencing the length of the adjustment period: athlete age, previous experiences/exposure,
12
13 355 injury history, personality and team culture/environment. Athlete 9 highlights how previous
14
15 356 experiences and team culture, can affect the attitudes of athletes, reducing the adjustment
16
17 357 period:

18
19
20
21 358 *'Our attitudes have definitely changed just because like anything you get used to doing*
22
23 359 *things. I remember when first time any teams decided to start wearing GPS... So many*
24
25 360 *players would just say, oh no, I can't wear this in training. Oh, It's not comfortable. I don't*
26
27 361 *want to do it. I don't want to train in that. And then it very slowly just becomes the norm and*
28
29 362 *people don't even think about it now.'* Athlete 9.

30
31
32
33 363 The older the athlete, the more likely they are to appreciate novel monitoring strategies,
34
35 364 especially when they may affect career longevity, as highlighted by athlete 7:

36
37 365 *'When I started, I would have said, you don't need it (GPS). What do you actually need it*
38
39 366 *for? But now, once you actually look at it, especially for you guys that are monitoring it. I*
40
41 367 *would have never thought about player loads, or watching how much you cover in relation*
42
43 368 *to injuries. I thought it was really good. Ever since I came to this club, I've had a few*
44
45 369 *injuries, and my view has changed. I took a bit of interest. Especially when you get a bit*
46
47 370 *older, with injuries and stuff, making sure you hit your markers to be where you need to*
48
49 371 *throughout the season.'* Athlete 7.

50
51
52
53 372 Athlete 1 highlights that both previous experience and injury history have impacted the
54
55 373 adjustment period, reinforcing the idea that an athlete's past encounters with similar
56
57 374 monitoring strategies influence how respond. The greater the athlete's injury history, the
58
59
60

1
2
3 375 more frequently they are likely to be exposed to the monitoring strategy, therefore reducing the
4
5 376 adjustment period.

7
8 377
9 378 ***Specific Monitoring Tools***

10 379
11 380 Within this study, the specific monitoring tools were broken up into five key areas: GPS
12
13 381 monitoring, subjective wellness, strength monitoring, saliva monitoring and power monitoring.
14
15 382 Each monitoring tool was valued independently of each other.

16
17
18 383

19
20 384 ***Global Positioning Satellite (GPS) Monitoring***

21
22 385 The present study found GPS to be the most popular **monitoring tool for players to use and**
23
24 386 **most frequently cited monitoring tool during interviews.** GPS, for outfield players, was
25
26 387 often seen as the most useful monitoring tool, with its relevance to on pitch performance cited
27
28 388 as a reason;

29
30 389 *'I think it's the most relevant to the actual football' Athlete 3.*

31
32 390 The relevance to matchday performance appears to increase the importance aspect of the GPS.
33
34 391 Further conversations led to participants highlighting GPS as a positive psychological tool
35
36 392 performance.

37
38 393 ***'The more I understood the more I realised how important it was (GPS). Important up here***
39
40 394 ***(psychologically) to know that I have been hitting the numbers, so I should for being fit***
41
42 395 ***enough for performing.'*** Athlete 4.

43
44 396 Specifically, the numbers given as feedback, and comparisons to previous performance were
45
46 397 key markers in increasing confidence post injury.

47
48 398

49
50 399 ***Subjective Wellness***

1
2
3 400 Subjective wellness was seen as the most polarizing measure with distinctly contrast views
4
5 401 between athletes. The lack of objectivity, feedback and repercussions of wellness testing were
6
7 402 cited as negative aspects of the monitoring strategy;

8
9
10 403 *'I can't remember when I have done a wellness score in the morning, and I don't know*
11
12 404 *what's changed, whether I've had horrendous night's sleep or I feel awful.'* Athlete 9.

13
14 405 **Athlete 9's perspective suggests that without visible repercussions or adjustments to their**
15
16 406 **training based on the data provided, the test may be seen as a superficial exercise rather**
17
18 407 **than a valuable tool for performance enhancement or wellbeing. This highlights the need**
19
20 408 **for greater transparency and communication between athletes and coaching staff**
21
22 409 **regarding how subjective wellness data informs decision-making. Incorporating follow-**
23
24 410 **up actions or individualized feedback loops could help bridge this gap, enhancing athlete**
25
26 411 **buy-in and reinforcing the relevance of subjective measures in the overall monitoring**
27
28 412 **strategy.**

29
30
31 413 Positive comments including likelihood of reducing injuries, managing training loads and
32
33 414 helping 'stay fresh'.

34
35 415 *'I do actually fill it (Subjective Wellness Questionnaire) out now (compared to when I was*
36
37 416 *younger). I see the importance of it now, when I am feeling sore, or my groin is tight, and*
38
39 417 *you guys (staff) will know before I am even in the building. I previously thought when I*
40
41 418 *was younger, it doesn't matter about sleep and soreness. Positively, even if training doesn't*
42
43 419 *change, you might adapt your gym programme to help.'* Athlete 1.

44
45 420 These contrasting views raise an interesting point about the individual differences for
46
47 421 monitoring tools and strategies. **Often a one size fits all approach may be taken with**
48
49 422 **monitoring team sport athletes. However,** individuals may not all be treated equally, with
50
51 423 player injury history, importance and attitude all affecting the coach's decision making.

52
53
54 424

55
56
57
58
59
60

1
2
3 425 *Saliva Monitoring*

4
5 426 The lack of education and feedback reduces the perceived importance of saliva monitoring, as
6
7
8 427 illustrated by Athlete 1's experience:

9
10 428 *'I didn't really understand the feedback part of it. And what for example, if we are fatigued,*
11
12 429 *what changed kind of thing after that.'* Athlete 1.

13
14 430 **Athlete 1's response highlights how the unfamiliarity with saliva testing, as a novel**
15
16
17 431 **monitoring tool, creates uncertainty about its relevance and practical application. This**
18
19 432 **athlete's remarks suggest that an adjustment period, accompanied by more**
20
21
22 433 **comprehensive education and consistent feedback, is necessary to reinforce the**
23
24 434 **importance of the test. By clearly demonstrating how the results influence training,**
25
26 435 **recovery, and overall performance, practitioners can help bridge this knowledge gap and**
27
28 436 **foster greater engagement.**

29
30 437 **Similarly, Athlete 10 echoes this sentiment, revealing further evidence of the disconnect**
31
32
33 438 **between the introduction of saliva testing and its perceived value:**

34
35 439 *'This was a new one (saliva testing), and I didn't really understand what you was getting*
36
37 440 *out of that. I know you've explained it. But I get that, if that is the next level for better*
38
39 441 *recovery, then I'm all for it. Because this was introduced this season for the first time, and*
40
41 442 *I didn't see any feedback from it, not sure if I was educated enough on it. That was the one*
42
43 443 *to be fair, that I could do with learning more about.'* Athlete 10

44
45
46 444 **Athlete 10's willingness to adopt new methods, provided they understand their purpose**
47
48
49 445 **and outcomes, highlights the need for continuous communication and education. Despite**
50
51 446 **initial explanations, the absence of visible results or actionable insights reduces the**
52
53 447 **perceived value of saliva testing. Athlete 1's unfamiliarity with the technology further**
54
55 448 **emphasizes the need for greater exposure and modelling to reshape perceptions.**
56
57 449 **Practitioners can enhance engagement by demonstrating how saliva monitoring benefits**
58
59
60

1
2
3 450 **performance, reinforcing its importance through follow-up discussions and personalized**
4
5 451 **feedback. Ultimately, bridging the gap between data collection and athlete understanding**
6
7 452 **is essential for maximizing the impact of this monitoring tool.**
8
9

10 453

11 454 *Strength Monitoring Tools*

12
13
14 455 Within this study, the strength monitoring tools consisted of the Vald Nordbord and Vald
15
16 456 Forceframe (Vald Performance, QLD). The objective nature of the strength data was frequently
17
18 457 highlighted as a positive. Clear instant visual feedback, coupled with value by highlighting how
19
20 458 the monitoring tool might influence an athlete's physical programme were seen positively by
21
22 459 athletes;

23
24
25 460 *It's hard data that's not subjective... Every single time the scores are there, you can't argue*
26
27 461 *with it. And it is what it is. The physios and, you guys, sports scientists, are using that data*
28
29 462 *and trying to affect things...So I think that was really good because it was objective... And*
30
31 463 *then I could see what's been done with the information,' Athlete 5.*

32
33
34 464 **This objective and transparent approach fostered trust in the testing process, reinforcing**
35
36 465 **the importance of the data and increasing athlete engagement. Below shows a further**
37
38 466 **quote from athlete 1, in reference to the strength testing and their injury history:**

39
40
41 467 *'Um, for example, I've not been having any knee problems. Cause I did start doing things*
42
43 468 *right with my knee and I didn't, you know, think, oh, I don't need to do that... I started*
44
45 469 *taking things a bit more seriously when I saw the importance of it. Um, especially with my*
46
47 470 *knee and the Nordbord and stuff like that'. Athlete 1*

48
49
50 471 **The visible impact of the results on their training programmes further solidified the**
51
52 472 **athletes' perception of the strength monitoring strategies as valuable and essential to their**
53
54 473 **physical development.**

55
56
57 474

58
59
60

1
2
3 475 *Power Monitoring*

4
5 476 Within this study, the power monitoring consisted of vertical counter movement jumps on the
6
7 477 Vald ForceDecks (Vald Performance, QLD) Relevance to performance ‘on the pitch’, has been
8
9 478 shown to be one of the areas increasing an athlete’s perceived importance of a monitoring
10
11 479 strategy. The 2 goalkeepers in the study highlighted the CMJ test as the most relevant, and
12
13 480 most highly valued monitoring tool.

14
15 481 *‘I wanted to get the biggest jump that I could and make them check that my power*
16
17 482 *programs and my strength programs are working. I could track my progress and, and it*
18
19 483 *was something that I could take outside onto the grass.’ Athlete 5.*

20
21 484 **This statement reflects the athlete’s recognition of the test’s direct impact on their**
22
23 485 **physical development and performance. Given the power-based demands of goalkeeping**
24
25 486 **– where explosive jumps closely mirror matchday actions – the CMJ test aligns naturally**
26
27 487 **with their role, reinforcing its perceived value. Conversely, for outfield athletes, the CMJ**
28
29 488 **test received mixed feedback. Some questioned its significance, citing a perceived**
30
31 489 **disconnect between test results and their on-field performance.**

32
33 490 *‘It (Power Testing) didn’t really feel like it was going to have an effect on what I was doing...*
34
35 491 *If my scores weren’t as high, it didn’t really feel like all that’s going to stop me from*
36
37 492 *playing,’ Athlete 4.*

38
39 493 **This reflects a belief that lower scores carried minimal consequences for training or**
40
41 494 **selection, diminishing motivation to engage fully with the test. The disparity between**
42
43 495 **goalkeepers and outfield players underscores the need for tailored communication and**
44
45 496 **clearer links between power monitoring outcomes and individual performance objectives**
46
47 497 **to enhance engagement across all athlete groups.**

48
49 498
50 499 **Discussion**
51
52
53
54
55
56
57
58
59
60

1
2
3 500 This study assessed elite soccer players' attitudes and perceptions toward athlete monitoring
4
5 501 using questionnaires and semi-structured interviews. The findings offer novel insights into how
6
7 502 soccer athletes perceive specific monitoring tests and the factors influencing the formation of
8
9 503 their attitudes. To the best of the author's knowledge, this is the first attempt to explore athlete
10
11 504 viewpoints on monitoring tools and discern how perceptions vary based on the monitoring
12
13 505 method employed. This research offers a unique insight into professional male soccer players'
14
15 506 attitudes toward monitoring strategies, highlighting how the adjustment period, feedback, and
16
17 507 education shape their perceptions. It enables practitioners to identify ways to optimise the
18
19 508 effectiveness of the monitoring systems in use.
20
21
22
23

24 509

25
26 510 The players' perception seemed to be influenced by the perceived importance of the
27
28 511 implemented monitoring strategy. For example, the more the athlete could see the translation
29
30 512 from the monitoring tool to their on-field performance, the more positively the athlete viewed
31
32 513 the monitoring tool. Specifically, the importance of a test in relation to their matchday
33
34 514 performance such as the countermovement jump testing for goalkeepers. Whereas the saliva
35
36 515 test was highlighted as having a lack of link between monitoring strategy and on field
37
38 516 performance. The athlete's perception of importance of a specific test was repeatedly
39
40 517 highlighted throughout the study. **By prioritizing monitoring tools that have a clear, visible**
41
42 518 **impact on performance and ensuring athletes understand how the data translates to their**
43
44 519 **development, practitioners can enhance engagement and compliance. This finding**
45
46 520 **suggests that involving athletes in the feedback process, explaining the purpose of each**
47
48 521 **test, and demonstrating how results drive individualized training adjustments can foster**
49
50 522 **greater trust and buy-in. Previous research²⁵ on GPS monitoring in soccer similarly**
51
52 523 **found that athletes regarded GPS as crucial, particularly for injury prevention, though**
53
54 524 **less significant for player retention. The current study expands on these findings by**
55
56
57
58
59
60

1
2
3 525 **examining a broader range of monitoring tools beyond GPS alone. Results indicate that**
4
5 526 **athletes consistently associate monitoring strategies with injury prevention, reinforcing**
6
7 527 **prior findings²⁵. However, the study also revealed that tests perceived as less impactful**
8
9 528 **were often associated with limited follow-up or lack of meaningful consequences. Athletes**
10
11 529 **frequently cited that tests lacking visible results or post-test support diminished their**
12
13 530 **perceived importance. This aligns with prior studies²⁴, which observed that the absence**
14
15 531 **of feedback or educational reinforcement lowered the perceived value of monitoring**
16
17 532 **tools. Conversely, tests that were perceived to influence playing time, coach decision-**
18
19 533 **making, or team selection – such as GPS – were more likely to be valued, especially when**
20
21 534 **results were shared visually with both coaches and athletes. Understanding why athletes**
22
23 535 **perceive certain monitoring strategies as more important, particularly when linked to**
24
25 536 **performance feedback and matchday outcomes, can help practitioners optimize**
26
27 537 **engagement and drive greater adherence to testing protocols. This approach ensures**
28
29 538 **monitoring tools not only support injury prevention but also enhance performance**
30
31 539 **outcomes, maximizing the overall effectiveness of physical assessments.**
32
33
34
35
36
37
38

39 540 **The results of this study suggest** that player adherence might be connected to the test's
40
41 541 **significance, but adherence critically relied on both visual and verbal feedback. While**
42
43 542 **feedback is essential, it can be delivered through verbal or visual communication. All**
44
45 543 **players highlighted feedback within this study as important, with instant visual feedback**
46
47 544 **frequently cited as beneficial, especially when in relation to previous performance. Research**
48
49 545 **demonstrated that soccer players prefer their data to be compared with players in a similar**
50
51 546 **position, thereby fostering competition with elite male soccer players to enhance motivation**
52
53 547 **for a given test²⁵. To maximize player engagement and adherence, practitioners should**
54
55 548 **prioritize delivering immediate visual feedback alongside verbal communication,**
56
57 549 **ensuring that performance metrics are contextualized against peers in similar positions.**
58
59
60

1
2
3 550 **This comparative approach can enhance motivation by fostering healthy competition,**
4
5 551 **ultimately driving improved performance and buy-in for monitoring strategies.** This
6
7 552 motivation, particular in relation to GPS, may have a direct relationship with match day
8
9 553 performance or selection. Whilst direct comparisons between positions can foster motivation,
10
11 554 understanding the context of the data is crucial. Variables such as the quality of opposition⁴⁵,
12
13 555 match outcome⁴⁶ formation⁴⁷ and playing position⁴⁸ can all affect physical matchday
14
15 556 performance. The ease of access to data and information within the current study was also
16
17 557 emphasised as important, with suggestions of apps for regular mobile visual feedback, likely
18
19 558 to enhance their interest in the athlete monitoring process. Similar to previous research²⁵, the
20
21 559 ease of access to the data was also view important with the preferred options of the data to be
22
23 560 shared in the changing room, where there is large exposure. All the above are in line with
24
25 561 previous literature highlighting that feedback is important for continued athlete engagement²⁶.
26
27 562 Further recent research disclosed that 44% of practitioners working in elite sport in the UK,
28
29 563 thought that not enough feedback was given to athletes around the athlete monitoring process⁴⁹.
30
31 564 This is despite practitioners placing value and importance upon feedback for athletes¹⁴. **All of**
32
33 565 **the interviewees emphasized feedback as a key area, with only 30% mentioning the lack**
34
35 566 **of feedback provided for any specific test.** Reasons for a lack of feedback could include
36
37 567 limited time with athletes or an overload of information making it difficult for practitioners to
38
39 568 decipher the important and relevant information⁵⁰. Within the current study, feedback was
40
41 569 limited for saliva and wellness testing, where performance was only fed back when scores
42
43 570 deviated significantly from the norm. This lack of feedback may have contributed to the lack
44
45 571 of importance placed on each tool by the athletes. This observation highlights where room
46
47 572 could be made to improve and increase athlete's perceived importance through greater
48
49 573 feedback. Regular and quick visual and verbal feedback, linked to both previous and potential
50
51 574 on field performance can help to improve an athlete's perception of athlete monitoring tools.
52
53
54
55
56
57
58
59
60

1
2
3 575 Limited feedback may also be tied to a lack of education regarding a specific tool or task.
4
5 576 Although there is limited research on the effects of education on soccer players, insufficient
6
7 577 education about a novel monitoring tool has been linked to increased negative perceptions of
8
9 578 the tool, ultimately resulting in limited feedback. This meant that athletes struggled to grasp
10
11 579 the tool's importance for performance. **Previous research found a 4-week nutritional**
12
13 580 **educational intervention including 4 x 30 minute lectures to significantly improve the athletes**
14
15 581 **understanding on nutrition**⁵¹. This research is based on youth athletes, who may respond
16
17 582 differently to senior professional athletes. Previous research has already highlighted the
18
19 583 logistical difficulty and willingness of players to participate in additional activities¹¹. Finding
20
21 584 the most time efficient, captivating way of educating athletes, and highlighting the importance
22
23 585 to their career, is crucial for practitioners to increase adherence and interest⁵². Interesting
24
25 586 research focusing on learning styles amongst elite team sport athletes, found very few athletes
26
27 587 to have a visual learning style preference **alone**, with male athletes most popular form of
28
29 588 learning kinaesthetic **or a mixed model**⁵³. This highlights the limited effectiveness of visual
30
31 589 lectures and presentations **alone**, which are often the default approach for educating team sport
32
33 590 athletes⁵¹. Instead, hands-on learning that demonstrates the use, effectiveness, and importance
34
35 591 of the equipment may be more impactful for efficient education. **Practitioners providing**
36
37 592 **clear, real-time feedback and education during practical equipment trials could address**
38
39 593 **this issue directly. Combining this approach with insights into how the equipment**
40
41 594 **influences physical performance can further enhance athletes' engagement and**
42
43 595 **receptiveness to monitoring tools.**
44
45 596 **An interesting concept that came out of this study, was the idea that each athlete will have**
46
47 597 **an individual adjustment period after first being exposed to a new monitoring system. It**
48
49 598 can be affected by several areas, one of which was previous experiences/exposure. Exposure
50
51 599 could be in the form of a role model⁵⁴. Prior exposure seeing other athletes using a specific
52
53
54
55
56
57
58
59
60

1
2
3 600 monitoring tool, may shorten the adjustment period. As highlighted by Athlete 1, the saliva
4
5 601 testing is not something they had seen or heard of before, which may lead to a longer adjustment
6
7 602 period. Previous research highlight how coaches can use observational learning theory to
8
9 603 influence athletes⁵⁵. By highlighting and showing elite role models using a particular tool, this
10
11 604 may help to shorten the adjustment period and increase the athlete's interest⁵⁶.

12
13
14 605 **Practitioners should adopt a blended approach, combining immediate visual and verbal**
15
16 606 **feedback with hands-on, kinaesthetic learning of the monitoring tool. Simultaneously,**
17
18 607 **educating athletes about the tool's purpose and benefits ensures the monitoring process**
19
20 608 **is both engaging and effective.**

21 22 23 24 25 609 *Reflections and Evaluation*

26
27 610 This study reflects the monitoring strategies and attitudes of **players specific to one soccer**
28
29 611 **team**, gaining in depth understanding. Further research now needs to understand the different
30
31 612 monitoring strategies and attitudes that may be generated from other clubs **and sports** and their
32
33 613 approaches. The information can then be generalised across a wider scale. Of the 2 goalkeepers
34
35 614 interviewed in the study, both highlighted the CMJ power test as the most relevant, and most
36
37 615 highly valued monitoring tool, in comparison to the GPS for outfielders. The importance and
38
39 616 relevance to their on-field performance was cited as the main reason for this perception of
40
41 617 increased relevance. Further research could focus more on the attitudes and monitoring
42
43 618 strategies of goalkeepers in comparison to outfield athletes, to establish further the differences
44
45 619 between these two groups. **Additionally, there is a need to educate both players and staff**
46
47 620 **on the complexity of the feedback provided. Specifically, regarding GPS and matchday**
48
49 621 **data, does their perception of a good performance correlate with running longer**
50
51 622 **distances? By educating players, their understanding of what the monitoring data**
52
53 623 **represents and how it is used may shift, influencing the way they engage with this**
54
55
56
57
58
59
60

1
2
3 624 **information. While the exact nature of this interaction is uncertain, it could ultimately**
4
5 625 **alter their perspective on what is most important and relevant to them as players.**
6
7
8

9 626 The current literature surrounding athlete attitudes towards monitoring processes in elite sport
10
11 627 is limited, with this study providing unique insight into attitudes across a range of monitoring
12
13 628 processes. The researcher of this study, previously worked as an employed member of support
14
15 629 staff, working closely with the participants of the study. At the time of interviews, the
16
17 630 researcher was an independent interviewer, which allowed for a unique honest perspective to
18
19 631 be given by the athletes in the study. The current study shows the potential usefulness of data
20
21 632 triangulation, with two parts to the study. Despite the questionnaires showing little link between
22
23 633 age, experience and attitudes towards monitoring, the interviews highlighted that the older
24
25 634 athletes tend to appreciate monitoring more for injury prevention to improve career longevity.
26
27 635 The initial questionnaire analysis also found that views towards athlete monitoring were
28
29 636 positive on the whole, whereas the interviews showed that the athletes believed it to be positive
30
31 637 because it provides feedback.
32
33
34
35
36
37

38 638 Player perceptions of monitoring strategies implemented in elite soccer have been discussed in
39
40 639 depth within this study. Further research may wish to focus more on the perception of the
41
42 640 technical and lead coaching staff. These individuals will often be the key decision makers at a
43
44 641 soccer club, therefore understanding their perceptions of monitoring, and how it affects their
45
46 642 decision making, is crucial for sports science practitioners. The current research also highlights
47
48 643 the vast importance of regular feedback and conversations with athletes around each
49
50 644 monitoring strategy. Without proper guidance, feedback and education, specific monitoring
51
52 645 tools can be viewed as meaningless and unimportant. Understanding the reason why this does
53
54 646 not always happen is crucial, whether it is related to time availability, coach-athlete
55
56 647 relationship, or the lack of perceived importance. Efforts of the coach team should be invested
57
58
59
60

1
2
3 648 into improving the buy-in of athletes, support staff and the organisation²⁴. Practitioners should
4
5 649 decide the volume of testing based on the staff availability, to ensure thorough feedback and
6
7 650 education can be utilised for each test.
8
9

10 651

11
12 652 *Conclusion*

13
14 653 This mixed methods study was conducted as a real-world applied example for other
15
16 654 practitioners seeking to improve and gain insight into the perception of their monitoring
17
18 655 strategies. **By prioritizing monitoring tools that clearly impact performance and ensuring**
19
20
21 656 **athletes understand how the data supports their development, practitioners can boost**
22
23 657 **engagement and compliance. Providing real-time visual and verbal feedback and**
24
25 658 **education throughout the monitoring process, along with insights into how the tools affect**
26
27 659 **physical performance, will further enhance athlete receptiveness.**

Theme	Sub-Theme
Feedback	- Longitudinal Monitoring
	- Readiness to Train
	- Objective Data
	- Conversations
	- Visual Feedback
Education	- Lack of Education
	- Transparency of Data Usage
Adjustment Period	- Athlete Age
	- Previous Experiences/Exposure
	- Injury History
	- Personality Type
	- Team Culture & Environment
Specific Monitoring Tools	- GPS
	- Subjective Wellness
	- Saliva Monitoring
	- Strength Monitoring Tools
	- Power Monitoring

Table 3. Breakdown of key themes
299x304mm (144 x 144 DPI)

1
2
3 **1 Modified Athlete Attitudes and Beliefs Questionnaire**

4 **2 Section A: Background**

- 5 3 1. Name
6 4 2. How Old are you?
7 5 3. How many years have you been playing as a professional athlete?
8 6 4. How many years have you been a professional athlete at Birmingham City FC?
9 7 5. How many clubs have you played for professionally?
10 8 6. How many years did you spend at an academy?
11 9

12
13
14 **10 Section B: Views on Athlete Monitoring (7 Point Likert Scale)**

- 15 11 7. Overall, at this club, do you think the use of athlete monitoring through GPS,
16 12 wellness, saliva, strength and power testing is: (Extremely good → Quite Good →
17 13 Slightly Good → Neither → Slightly Bad → Quite Bad → Extremely Bad)
18 14 8. At this club, I think that the GPS monitoring is: (Extremely good → Extremely Bad)
19 15 9. At this club, I think that wellness monitoring is: (Extremely good → Extremely Bad)
20 16 10. At this club, I think that strength monitoring is: (Extremely good → Extremely Bad)
21 17 11. At this club, I think that power monitoring is: (Extremely good → Extremely Bad)
22 18 12. At this club, I think that saliva monitoring is: (Extremely good → Extremely Bad)
23 19 13. At this club, when it comes to athlete monitoring, I think there is: (Extremely Not
24 20 Enough → Extremely Too Much)
25 21 14. Athlete monitoring will help me to improve my physical performance. (Extremely
26 22 Unlikely → Extremely Likely)
27 23 15. Athlete monitoring will help me to improve my availability. (Extremely Unlikely →
28 24 Extremely Likely)
29 25 16. I am very motivated to complete any athlete monitoring tests to the best of my ability.
30 26 (Extremely Unlikely → Extremely Likely)
31 27 17. Athlete monitoring will help the coaches with team selection. (Extremely Unlikely →
32 28 Extremely Likely)
33 29 18. I understand what athlete monitoring tools are used for. (Extremely Unlikely →
34 30 Extremely Likely)
35 31

36
37
38
39 **32 Section C: Additional Information (Open Long Form Answers)**

- 40 33 19. What are some of the things you like about athlete monitoring?
41 34 20. What are some of the things you do not like about athlete monitoring?
42 35 21. Can you rank these monitoring tools in order of importance (1 = most important, 5 =
43 36 least important)? GPS, Wellness, Saliva Testing, Strength Testing, Power Testing.
44 37 22. Are there any other comments or suggestions you would like to make about athlete
45 38 monitoring.
